ABSTRACT OF THE DISCLOSURE:

A method for allowing a partial instruction to be executed in a fixed point unit pipeline during the instruction dispatch cycle creates a mask used to select which bits of the operands

- 5 participate in a future logical operation of the fixed point unit back a cycle to the instruction dispatch stage of the fixed point unit. As an S/390 System improvement applicable to other computers, the mask is determined and created two cycles ahead of execution, or two cycles before the mask is actually used. Also,
- 10 in the method used for moving the mask generation back by one cycle, mask generation overlaps the dispatch stage in the I-unit, and this provides a handshake between the I-unit and E-unit of the fixed point unit of the central processor unit of the computer system. The control setting selection process occurs in
- 15 a predetermination cycle stage or e-1 (em1) stage for the mask generation and the register file read address. Speculative handshaking allows the E-1 stage to be created with no impact to the last stage of the I-Unit, such that no additional logic is needed and cycle time is not jeopardized. Also, the E-1 stage of
- 20 an instruction overlaps with the execution stages of previous instructions.
